12   Abstract

13         Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is emerging as an important proxy for  
14   deep ocean circulation in the past. In order to allow for a direct model-data  
15   comparison and to improve our understanding of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity  
16   ratio, we implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the ocean component of the Community  
17   Earth System Model (CESM). In addition to the fully coupled implementation of the  
18   scavenging behavior of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  with the active marine ecosystem module (p-  
19   coupled), another form of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  have also been implemented with  
20   prescribed particle flux fields of the present climate (p-fixed). The comparison of the  
21   two forms of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  helps to isolate the influence of the particle fluxes from  
22   that of ocean circulation. Under present day climate forcing, our model is able to  
23   simulate water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity and sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity  
24   ratio in good agreement with available observations. In addition, the p-coupled and  
25   p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratios behave similarly over large areas of low  
26   productivity on long timescale to freshwater forcing, but can differ substantially in  
27   some regions of high productivity and on short timescale, indicating the importance  
28   of biological productivity in addition to ocean transport. Therefore, our model  
29   provides a potentially powerful tool to help our interpretation of sediment  
30    $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions and to improve our understanding of past ocean  
31   circulation and climate changes.

32     **1. Introduction**

33         Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio has been used as a proxy for ocean  
34 circulation in the past (e.g. Yu et al. 1996; McManus et al. 2004; Gherardi et al.  
35 2009).  $^{231}\text{Pa}$  (32.5 ka half-life) and  $^{230}\text{Th}$  (75.2 ka half-life) are produced at a  
36 constant rate approximately uniformly in the ocean by the  $\alpha$  decay of  $^{235}\text{U}$  and  $^{234}\text{U}$ ,  
37 respectively, with a production activity ratio of 0.093 (Henderson and Anderson,  
38 2003). Water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are subject to particle scavenging and  
39 transport to sediments (Bacon and Anderson, 1982; Nozaki et al., 1987). Different  
40 scavenging efficiency results in different ocean residence time:  $^{231}\text{Pa}$  has a residence  
41 time of approximately 111 years and  $^{230}\text{Th}$  has a residence time of approximately 26  
42 years (Yu et al., 1996). Longer residence time of  $^{231}\text{Pa}$  than  $^{230}\text{Th}$  makes  $^{231}\text{Pa}$  more  
43 subject to ocean transport and therefore in the modern ocean about 45% of  $^{231}\text{Pa}$   
44 produced in the Atlantic is transported to the Southern Ocean (Yu et al., 1996),  
45 resulting a lower than 0.093 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in the North Atlantic  
46 and higher than 0.093 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in the Southern Ocean.

47         The application of the principle above to interpret sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as  
48 the strength of Atlantic meridional overturning circulation (AMOC), however, can be  
49 complicated by other factors, leading to uncertainties in using  $^{231}\text{Pa}/^{230}\text{Th}$  as a proxy  
50 for past circulation (Keigwin and Boyle, 2008; Lippold et al., 2009; Scholten et al.,  
51 2008). In addition to the ocean transport, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is also influenced by  
52 particle flux and composition (Chase et al., 2002; Geibert and Usbeck, 2004;  
53 Scholten et al., 2008; Siddall et al., 2007; Walter et al., 1997). The region of a higher  
54 particle flux tends to have a higher  $^{231}\text{Pa}/^{230}\text{Th}$  (Kumar et al., 1993; Yong Lao et al.,  
55 1992), which is referred to as the “particle flux effect” (Siddall et al., 2005). Regional  
56 high particle flux in the water column will favor the removal of isotopes into the  
57 sediment, which leads to more isotopes transported into this region due to the  
58 down-gradient diffusive flux and subsequently more removal of isotopes into the  
59 sediment. Since  $^{231}\text{Pa}$  has a longer residence time, this effect is more prominent on  
60  $^{231}\text{Pa}$  than on  $^{230}\text{Th}$  and therefore sediment  $^{231}\text{Pa}/^{230}\text{Th}$  will be higher in high  
61 productivity regions. Also, opal is able to scavenge  $^{231}\text{Pa}$  much more effectively than  
62  $^{230}\text{Th}$ , leading to higher  $^{231}\text{Pa}/^{230}\text{Th}$  in high opal flux regions such as the Southern

63 Ocean (Chase et al., 2002). Moreover, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is suggested to record  
64 circulation change only within 1,000 m above the sediment, instead of the whole  
65 water column, complicating the interpretation of sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
66 reconstructions (Thomas et al., 2006). For example, sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
67 approaching 0.093 during Heinrich Stadial event 1(HS1) from the subtropical North  
68 Atlantic is interpreted as the collapse of AMOC (McManus et al., 2004). If sediment  
69  $^{231}\text{Pa}/^{230}\text{Th}$  only records deepest water mass, it is possible that during HS1, AMOC  
70 shoals, as opposed to a fully collapse, yet an increase of deep water imported from  
71 the Southern Ocean featuring high  $^{231}\text{Pa}/^{230}\text{Th}$  can increase the sediment  
72  $^{231}\text{Pa}/^{230}\text{Th}$  approaching the production ratio (0.093) (Thomas et al., 2006).  
73 Therefore, it is important to incorporate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  into climate models for a  
74 direct model-data comparison and to promote a thorough understanding of  
75 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as well as past ocean circulation.

76  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  have been simulated in previous modeling studies (Dutay et  
77 al., 2009; Luo et al., 2010; Marchal et al., 2000; Rempfer et al., 2017; Siddall et al.,  
78 2005). Marchal et al., (2000) simulates  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in a zonally averaged  
79 circulation model, using the reversible scavenging model of Bacon and Anderson,  
80 (1982). One step further, Siddall et al. (2005) extends Marchal et al., (2000) by  
81 including particle dissolution with prescribed particle export production in a 3-D  
82 circulation model. Rempfer et al., (2017) further couples  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  with active  
83 biogeochemical model and includes boundary scavenging and sediment  
84 resuspensions to improve model performance in simulating water column  $^{231}\text{Pa}$  and  
85  $^{230}\text{Th}$  activity. Here we follow previous studies to implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  into the  
86 Community Earth System Model (CESM). Our  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are coupled with  
87 active marine ecosystem model (“p-coupled”) and p-coupled  $^{231}\text{Pa}/^{230}\text{Th}$  is  
88 influenced by both ocean circulation change and particle flux change. To help to  
89 understand the influence of the particle flux, we have also implemented a “p-fixed”  
90 version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , for which the particle fluxes are fixed at prescribed  
91 values. Therefore, p-fixed  $^{231}\text{Pa}/^{230}\text{Th}$  is only influenced by ocean circulation change.  
92 By comparing the p-fixed  $^{231}\text{Pa}/^{230}\text{Th}$  with the p-coupled  $^{231}\text{Pa}/^{230}\text{Th}$ , we will be  
93 able to separate the effect of circulation change from particle flux change. In

94 addition, the p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be run without the marine ecosystem  
95 module, reducing computational cost by a factor of 3 in the ocean-alone model  
96 simulation, making it a computationally efficient tracer for sensitivity studies.

97 This paper describes the details of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CESM and serves as a  
98 reference for future studies using this tracer module. In section 2, we describe the  
99 model and the implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . In sections 3, we describe the  
100 experimental design. We will finally compare simulated  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  fields with  
101 observations, show model sensitivities on model parameter and also sediment  
102  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to freshwater forcing in Section 4.

103

## 104 **2. Model Description**

### 105 2.1 Physical Ocean Model

106 We implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the ocean model (Parallel Ocean Program  
107 version 2, POP2) (Danabasoglu et al., 2012) of CESM (Hurrell et al., 2013). CESM is a  
108 state-of-the-art coupled climate model and studies describing model components  
109 and analyzing results can be found in a special collection in Journal of Climate  
110 (<http://journals.ametsoc.org/topic/ccsm4-cesm1>). We run the ocean-alone model,  
111 which is coupled to data atmosphere, land, ice and river runoff under the normal  
112 year forcing of CORE-II data (Large and Yeager, 2008), using the low-resolution  
113 version of POP2 with a nominal  $3^\circ$  horizontal resolution and 60 vertical layers.

114

### 115 2.2 Biogeochemical component (BGC)

116 CESM has incorporated a marine ecosystem module that simulates biological  
117 variables (Moore et al., 2013). The marine ecosystem module has been validated  
118 against present day observations extensively (e.g. Doney et al., 2009; Long et al.,  
119 2013; Moore et al., 2002, 2004; Moore and Braucher, 2008). The implementation of  
120  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  requires particle fields:  $\text{CaCO}_3$ , opal and particulate organic carbon  
121 (POC). These particle fields can be obtained through the ecosystem driver from the  
122 ecosystem module (Jahn et al., 2015). The ecosystem module simulates the particle  
123 fluxes in reasonable agreement with the present-day observations. The pattern and  
124 magnitude of the annual mean particle fluxes ( $\text{CaCO}_3$ , opal, POC) leaving the

125 euphotic zone at 105m are similar to the satellite observations (Fig. 7.2.5 and 9.2.2  
126 in Sarmiento and Gruber 2006) (Fig. 1 a~c): particle fluxes are higher in the high  
127 productivity regions such as high latitudes and equatorial Pacific; opal flux is high in  
128 the Southern Ocean. The remineralization scheme of particle is based on the ballast  
129 model of Armstrong et al., (2002). Detailed parameterizations for particle  
130 remineralization are documented in Moore et al., (2004) with temperature  
131 dependent remineralization length scales for POC and opal. We do not consider dust  
132 because it is suggested to be unimportant for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  fractionation (Chase et  
133 al., 2002; Siddall et al., 2005).

134

### 135 2.3 $^{231}\text{Pa}$ and $^{230}\text{Th}$ implementation

136  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are produced from the  $\alpha$  decay of  $^{235}\text{U}$  and  $^{234}\text{U}$  uniformly  
137 everywhere at constant rate  $\beta^i$  ( $\beta^{\text{Pa}} = 2.33 \times 10^{-3} \text{ dpm m}^{-3} \text{ yr}^{-1}$ ,  $\beta^{\text{Th}} = 2.52 \times 10^{-2} \text{ dpm m}^{-3}$   
138  $\text{yr}^{-1}$ ).  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are also subjective to radioactive decay with the decay  
139 constant of  $\lambda^i$  ( $\lambda^{\text{Pa}} = 2.13 \times 10^{-5} \text{ yr}^{-1}$ ,  $\lambda^{\text{Th}} = 9.22 \times 10^{-6} \text{ yr}^{-1}$ ).

140 Another important process contributes to  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity is the  
141 reversible scavenging by sinking particles (Bacon and Anderson, 1982), which  
142 describes the adsorption of isotopes onto sinking particles and desorption after the  
143 dissolution of particles. This process transports  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  downward and  
144 leads to a general increase of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity with depth. The reversible  
145 scavenging considers total isotope activity ( $A_t^i$ ) as two categories (Eq. (1)):  
146 dissolved isotopes ( $A_d^i$ ) and particulate isotopes ( $A_p^i$ ) (superscript i refers to  $^{231}\text{Pa}$   
147 and  $^{230}\text{Th}$ ) and  $A_p^i$  is the sum of the isotopes associated with different particle types  
148 ( $A_{j,p}^i$ ) (subscript j refers to different particle types:  $\text{CaCO}_3$ , opal and POC):

$$149 A_t^i = A_d^i + A_p^i = A_d^i + \sum_j A_{j,p}^i \quad (1)$$

150

151 Dissolved and particulate isotopes are assumed to be in equilibrium, which is a  
152 reasonable assumption in the open ocean (Bacon and Anderson, 1982; Henderson et

153 al., 1999; Moore and Hunter, 1985). The ratio between the particulate isotope  
154 activity and the dissolved isotope activity is set by a partition coefficient, K (Eq. (2)):

$$155 \quad K_j^i = \frac{A_{j,p}^i}{A_d^i \cdot R_j} \quad (2)$$

156

157 , where  $R_j$  is the ratio of particle concentration ( $C_j$ ) to the density of seawater  
158 ( $1024.5 \text{ kg m}^{-3}$ ). Subscript j refers to different particle types (CaCO<sub>3</sub>, opal and POC).  
159 Values of partition coefficient K used in our control simulation follows Chase et al.,  
160 2002 and Siddall et al., 2005 (Table 2).

161 Particulate isotopes ( $A_p^i$ ) will be transported by sinking particles, which is  
162 described by  $w_s \frac{\partial A_p^i}{\partial z}$  (Eq. (3)), where  $w_s$  is the sinking velocity. We don't  
163 differentiate between slow sinking small particles and rapid sinking large particles  
164 as in Dutay et al., (2009) and consider all particles as slowly sinking small particles  
165 with sinking velocity of  $w_s = 1000 \text{ m yr}^{-1}$  (Arsouze et al., 2009; Dutay et al., 2009;  
166 Kriest, 2002), which is similar to Rempfer et al., (2017) and Siddall et al., (2005).  
167 Any particulate isotopes ( $A_p^i$ ) at the ocean bottom layer are removed from the  
168 ocean as sediment, which is the sink for the isotope budget. Detailed vertical  
169 differentiation scheme to calculate this term in the model is provided in the  
170 supplementary material. The reversible scavenging scheme applied here is the same  
171 as the neodymium implementation in POP2 (Gu et al., 2017).

172

173 Therefore, the conservation equation for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity can be  
174 written as

$$175 \quad \frac{\partial A_t^i}{\partial t} = \beta^i - \lambda^i A_t^i - w_s \frac{\partial A_p^i}{\partial z} + \text{Transport} \quad (3),$$

176 where the total isotope activity is controlled by decay from U (first term),  
177 radioactive decay (second term), reversible scavenging (third term) and physical  
178 transport by the ocean model (fourth term, including advection, convection and  
179 diffusion).  $A_p^i$  can be calculated by combining Eq. (1) and Eq. (2):

$$\begin{aligned} 180 \quad A_t^i &= A_d^i + A_d^i \cdot (K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}) \\ 181 \quad &= A_d^i \cdot (1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}), \end{aligned} \quad (4)$$

182 which leads to

$$A_d^i = \frac{A_t^i}{1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}}, \quad (5)$$

184 put this back to Eq. (1), we get

$$A_p^i = A_t^i \cdot \left(1 - \frac{1}{1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}}\right) \quad (6)$$

186

Particle fields used in the reversible scavenging can be either prescribed or simultaneously generated from the marine ecosystem module. Therefore, two forms of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are implemented in POP2: “p-fixed” and “p-coupled”. P-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  use particle fluxes prescribed as annual mean particle fluxes generated from the marine ecosystem module under present day climate forcing (Fig.1). P-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  use particle fluxes computed simultaneously from the marine ecosystem module. P-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be turned on at the case build time and the p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  requires the ecosystem module to be turned on at the same time.

196

Comparing with previous studies of modeling  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , our p-fixed version is the same as Siddall et al., (2002), except that different prescribed particle fluxes are used. The p-coupled version allows coupling to biogeochemical module, which is similar to Rempfer et al., (2017), but we do not include boundary scavenging and sediment resuspensions as in Rempfer et al., (2017) because boundary scavenging and sediment resuspensions are suggested to be unimportant to influence the relationship between  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  and AMOC strength (Rempfer et al., 2017).

205

206 3. Experiments

We run a control experiment (CTRL) and two experiments with different partition coefficients to show model sensitivity. We have both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL, but only p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in sensitivity experiments. Equilibrium partition coefficients for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  vary among different particle types and the magnitude of the partition coefficients for different particle types remains uncertain (Chase et al., 2002; Chase and Robert F, 2004; Luo and Ku, 1999). Since the control experiment in Siddall et al., (2005) is able to simulate major features of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  distributions, we use the partition coefficients from the control experiment in Siddall et al., (2005) in our CTRL (Table 2). Two sensitivity experiments are performed with decreased (EXP\_1) and increased (EXP\_2) partition coefficients by a factor of 5 (Table 2).

All the experiments are ocean-alone experiments with the normal year forcing by CORE-II data (Large and Yeager, 2008). The  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities are initiated from 0 in CTRL and are integrated for 2,000 model years until equilibrium is reached. EXP\_1 and EXP\_2 are initiated from 1,400 model year in CTRL and are integrated for another 800 model years to reach equilibrium.

Since sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in North Atlantic has been used to reflect the strength of AMOC, to test how sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in our model responds to the change of AMOC and the change of particle fluxes, we carried out a fresh water perturbation experiment (HOSING) with both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . Starting from 2,000 model year of CTRL, a freshwater flux of 1 Sv is imposed over the North Atlantic region of  $50^\circ\text{N} \sim 70^\circ\text{N}$  and the experiment is integrated for 1400 model years until both p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio have reached quasi-equilibrium. The partition coefficients used in HOSING are the same as in CTRL.

232

## 233 **4. Results**

### 234 4.1 Control Experiment

P-fixed and p-coupled version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL show identical results (Fig. 2-4). P-fixed and p-coupled dissolved and particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL are highly correlated with each other with correlations greater than 0.995 and

238 regression coefficients are all near 1.0 ( $R^2 > 0.995$ ). The correlation coefficient  
239 between p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratios in CTRL is 0.99  
240 and the regression coefficient is 0.9 ( $R^2 = 0.98$ ). This is expected because the particle  
241 fields used in p-fixed version are prescribed as the climatology of the particle fields  
242 used in the p-coupled version. Therefore, under the same climate forcing, p-fixed  
243 and p-coupled version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  should be very similar. For the discussion  
244 of results in CTRL below, we only discuss the p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ .

245 The residence time of both  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL are comparable with  
246 observations. The residence time is calculated as the ratio of global average total  
247 isotope activity and the radioactive ingrowth of the isotope. Residence time in CTRL  
248 is 118 yr for  $^{231}\text{Pa}$  and 33 yr for  $^{230}\text{Th}$  (Table 2), which are of the same magnitude as  
249 111 yr for  $^{231}\text{Pa}$  and 26 yr for  $^{230}\text{Th}$  in observation (Yu et al., 1996).

250 CTRL can simulate the general features of dissolved water column  $^{231}\text{Pa}$  and  
251  $^{230}\text{Th}$  activities. Dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities increase with depth in CTRL, as  
252 shown in two GEOTRACES transects (Deng et al., 2014; Hayes et al., 2015) in the  
253 Atlantic (Fig. 2 and 3). The dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities in CTRL are also at  
254 the same order of magnitude as in observations in the most of the ocean, except that  
255 simulated values are larger than observations in the abyssal, which is also the case  
256 in Siddall et al., (2005) and Rempfer et al., (2017) (their Fig. 2 and 3, experiment  
257 Re3d). Our model is unable to simulate the realistic dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
258 activities in abyssal because boundary scavenging and sediment resuspensions are  
259 not included in our model. With boundary scavenging and sediment resuspensions  
260 added, dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities in the abyssal should be greatly reduced  
261 (Rempfer et al., 2017).

262 A more quantitative model-data comparison is shown in Fig. 5. The linear  
263 regression coefficient between model results and observations (references of  
264 observations are listed in Table 3), an indication of model ability to simulate  $^{231}\text{Pa}$   
265 and  $^{230}\text{Th}$  activity (Dutay et al., 2009), is near 1.0 for dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  (1.02  
266 for  $[^{231}\text{Pa}]_d$  and 1.14 for  $[^{230}\text{Th}]_d$ ), suggesting that CTRL can simulate the dissolved  
267  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in good agreement with observations. However, the simulation of  
268 the particulate activity is not as good as the dissolved activity. Particulate activity is

269 overall larger than observation in the surface ocean and smaller than observation in  
270 the deep ocean for both particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . The regression coefficient for  
271 particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is 0.02 for  $[^{231}\text{Pa}]_p$  and 0.05 for  $[^{230}\text{Th}]_p$ . The poor  
272 performance in simulating water column particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities is also  
273 in previous modeling studies (Dutay et al., 2009; Siddall et al., 2005), because of  
274 similar modelling scheme are applied. However, the simulated  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  is in  
275 reasonable agreement with observations. The  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  along two GEOTRACES  
276 transects (Fig. 2 and 3) show the similar pattern and magnitude as in Rempfer et al.,  
277 (2017), consistent with observations. Decrease of  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  with depth is well  
278 simulated, which is suggested to be caused by the lateral transport of  $^{231}\text{Pa}$  from  
279 North Atlantic to Southern Ocean by AMOC (Gherardi et al., 2009; Lippold et al.,  
280 2011, 2012a; Luo et al., 2010; Rempfer et al., 2017).

281 The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in CTRL is overall consistent with observations  
282 (references of observations are listed in Table 3). The North Atlantic shows low  
283 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio as in observations because  $^{231}\text{Pa}$  is more subject  
284 to the southward transport by active ocean circulation than  $^{230}\text{Th}$  because of its  
285 longer residence time. The Southern Ocean maximum in the sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
286 activity ratio is also simulated in CTRL. High opal fluxes in the Southern Ocean,  
287 which preferentially removes  $^{231}\text{Pa}$  into sediment ( $K_{\text{opal}}^{^{231}\text{Pa}} > K_{\text{opal}}^{^{230}\text{Th}}$ ) (Chase et al.,  
288 2002), leading to increased sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio. In addition,  
289 upwelling in the Southern Ocean brings up deep water enriched with  $^{231}\text{Pa}$ , which is  
290 transported from the North Atlantic, to shallower depth and further contribute to  
291 the scavenging. CTRL can also produce higher sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in  
292 regions with high particle production (e.g. the Eastern equatorial Pacific, the North  
293 Pacific and the Indian Ocean) due to the “particle flux effect”. Specifically, in North  
294 Atlantic, the distribution of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  matches the distribution of  
295 particle, especially opal, production: sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is higher where opal  
296 production is high, and vice versa (Fig. 4 and Fig. 1c).

297

298 4.2 Sensitivity on partition coefficient K

299 In this section, we show model sensitivity on partition coefficient by  
300 increasing and decreasing the partition coefficient, K, by a factor of 5, but keep the  
301 relative ratio for different particles the same (Table 2). Our model shows similar  
302 model sensitivity as in Siddall et al., (2005) as discussed below.

303 As stated in Siddall et al., (2005), the isotope decay term in Eq. (3) is three  
304 orders of magnitude less than the production term. If we neglect the transport term  
305 and the decay term in Eq. (3) and assume particulate phase activity at the surface as  
306 0, when reach equilibrium, the activity of particulate phase will be as in Eq. (7). Eq.  
307 (7) combined with Eq.(2) and  $R_i = \frac{F}{w_s * \rho}$ , we can get Eq.(8). Under the assumption  
308 that there is isotope decay and ocean transport, Eq. (7) suggests that the particulate  
309 isotope activity depends on the production rate and settling velocity and will  
310 increase linearly with depth. Eq. (8) suggests that the dissolved isotope activity  
311 depends on the production rate, partition coefficient K and particle flux and will also  
312 increase linearly with depth. Any departure from this linear relationship with depth  
313 is due to ocean transport, which is suggested by observations (Bacon and Anderson,  
314 1982; Roy-Barman et al., 1996). Results of Eq. (7) and Eq. (8) can help to understand  
315 the differences in Exp\_1 and Exp\_2.

316 Increasing K will decrease water column dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities  
317 but won't change particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  too much (Fig. 6). Magnitude of  
318 dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in Exp\_1 (smaller K) is at least one order larger than that  
319 in Exp\_2 (larger K), while magnitude of particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in Exp\_1 and  
320 Exp\_2 is in the same order. As suggested by Eq. (8), if there is no isotope decay and  
321 no ocean transport, larger K will lead to smaller dissolved isotope activity but  
322 unchanged particulate activity. Intuitively, larger K will lead to more  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
323 attached to particles and further buried into sediment, which increases the sink for  
324 the  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  budget. With the sources for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  staying the same,  
325 dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  will be reduced. Increasing K will also reduce the vertical  
326 gradient of dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  as reversible scavenging act as the vertical  
327 transport and increase this vertical transport can decrease the vertical gradient.  
328 However, changes in the particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is relatively small (Fig. 6). Eq.

329 (7) suggests that particulate phase activity it is independent of K. Therefore,  
330 changing K will have limited influence on particulate phase activity.

331

$$A_p^i(z) = \frac{\beta^i}{w_s} \cdot z \quad (7)$$

332

$$A_d^i(z) = \frac{\rho\beta^i}{K^i F} \cdot z \quad (8)$$

333

334 Increasing K will also reduce the spatial gradient in sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
335 activity ratio and vice versa (Fig. 7). Larger K will decrease the  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
336 residence time and most isotopes produced in the water column are removed into  
337 sediment locally (Table 2). Therefore, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio becomes more  
338 homogeneous and approaching the production ration of 0.093 (Fig. 7b). The  
339 deviation (the root mean squared error) of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is 0.0726 in CTRL,  
340 0.0770 in Exp\_1 and 0.0739 in Exp\_2. Together with the water column isotope  
341 activity, it suggests that the partition coefficient in CTRL is of the right order of  
342 magnitude.

343

#### 344 4.3. Sediment $^{231}\text{Pa}/^{230}\text{Th}$ ratio in HOSING

345 Potential changes in the export of biogenic particles makes using  $^{231}\text{Pa}/^{230}\text{Th}$   
346 ratio to reconstructing AMOC strength under debate. In response to freshwater  
347 perturbation in the North Atlantic, both biological productivity and AMOC strength  
348 will change and will influence sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in different ways. Our model  
349 with p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can help to detangle these two effects. In  
350 this section, we examine the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  (p-fixed and p-coupled) response  
351 in the North Atlantic to idealized fresh water perturbation.

352 In HOSING, after applying freshwater forcing to the North Atlantic, AMOC  
353 strength quickly decreases to a minimum of 2 Sv (AMOC\_off) (Fig. 9a). During the  
354 AMOC\_off state, compared with CTRL with active AMOC (AMOC\_on), p-fixed  
355 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  shows an overall increase in the North Atlantic and a decrease  
356 in the South Atlantic (Fig. 10b) because of the reduced southward transport of  $^{231}\text{Pa}$

357 from the North Atlantic by AMOC, consistent with paleo proxy evidence there (e.g.  
358 Gherardi et al., 2005, 2009; McManus et al., 2004). The overall increase of sediment  
359  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic in response to the AMOC collapse can be seen  
360 more clearly in the time evolution of the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio averaged from  
361 20°N to 60°N in the North Atlantic (Fig.9b, green). Quantitatively, the  $^{231}\text{Pa}/^{230}\text{Th}$   
362 increases from 0.074 in AMOC\_on to 0.098 in AMOC\_off in the p-fixed version,  
363 approaching the production ration of 0.093. This increase of  $^{231}\text{Pa}/^{230}\text{Th}$  is also in  
364 the subtropical North Atlantic from the two sites near Bermuda Rise (Fig. 9e and f),  
365 which is of comparable magnitude with the change from LGM to HS1 in  
366 reconstructions there (McManus et al., 2004). In addition, the pattern of p-fixed  
367 (Fig.10a) sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio during the Atlantic in AMOC\_off state is similar  
368 to the opal distribution (Fig.1b) because, without active circulation, sediment  
369  $^{231}\text{Pa}/^{230}\text{Th}$  ratio is more controlled by particle flux effect, which is similar to the  
370 Pacific in CTRL. It is further noted that our p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in  
371 HOSING behaves similarly to that in Siddall et al., (2007).

372 The overall increase in p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North  
373 Atlantic is not homogenous and the magnitude of the change between AMOC\_on and  
374 AMOC\_off varies with location because of the distribution of particle flux, especially  
375 opal flux (Fig.9 and 10). The maximum increase in p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
376 ratio occurs near 40°N western Atlantic, where the opal production in our model is  
377 maximum in North Atlantic (Fig. 1b). It should be noted that the opal maximum in  
378 this region is not in the observation (Fig. 7.2.5 in Sarmiento and Gruber 2006).  
379 However, our sediment  $^{231}\text{Pa}/^{230}\text{Th}$  response in HOSING is self-consistent with the  
380 particle flux in our model. The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in this region during  
381 AMOC\_on is larger than production ratio of 0.093 because opal maximum provides  
382 extra  $^{231}\text{Pa}$  to this region (“particle flux effect”), which overwhelms the active ocean  
383 circulation transporting  $^{231}\text{Pa}$  southward outside this region (Fig. 9d, green). During  
384 AMOC\_off, without active ocean circulation, the particle flux effect becomes even  
385 stronger because less  $^{231}\text{Pa}$  is transported out of the North Atlantic and p-fixed  
386 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio gets even larger.

387 In most regions of the Atlantic, p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  shows a  
388 similar response to p-fixed  $^{231}\text{Pa}/^{230}\text{Th}$  in HOSING. The evolution of p-fixed and p-  
389 coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in HOSING are highly correlated (Fig.  
390 11a). The change of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio from AMOC\_on to AMOC\_off are  
391 similar in both p-fixed and p-coupled version (Fig.11b). The correlation between p-  
392 fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio change from AMOC\_on to AMOC\_off  
393 is 0.72 (1455points) and the linear regression coefficient is 0.71 ( $R^2 = 0.52$ ). High  
394 correlation between p-fixed and p-coupled response mainly happens over low  
395 productivity regions (Fig.1, 10, and 11), where circulation effect on sediment  
396  $^{231}\text{Pa}/^{230}\text{Th}$  is more important than the particle flux change in HOSING.

397 However, the responses of p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  to the  
398 fresh water forcing can differ significantly in high productivity regions because of  
399 the importance of the productivity change. With persistent freshwater forcing over  
400 the North Atlantic, most regions in the North Atlantic show reduced production of  
401  $\text{CaCO}_3$ , opal and POC (Fig. 8). Productivity in the North Atlantic is suggested to be  
402 halved during AMOC collapse because of increased stratification, which reduces  
403 nutrient supply from deep ocean (Schmittner, 2005). In our model, the productivity  
404 in the mid-latitude North Atlantic is indeed greatly reduced after the freshwater  
405 forcing is applied. For example, opal production from  $30^\circ\text{N}$ - $50^\circ\text{N}$  in the Atlantic at  
406 the end of HOSING is reduced by 50%~90% of its original value in CTRL. However,  
407 opal production increases in high latitude North Atlantic (north of  $50^\circ\text{N}$ ). The  
408 pattern of opal production changes with high opal production region shifts  
409 northward in HOSING (Fig. 8 d, e and f). These particle flux changes will influence  
410 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as discussed below.

411 North of  $50^\circ\text{N}$  in the Atlantic, the opal productivity increases during  
412 AMOC\_off (Fig. 8f) and will result an increase in sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . The increase  
413 caused by greater opal productivity enhances the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  increase  
414 caused by reduced AMOC. Therefore, the increase in p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
415 from AMOC\_on to AMOC\_off is larger than p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  change  
416 (Fig.9c).

417 In the mid-latitude North Atlantic, the opal productivity decreases during  
418 AMOC\_off (Fig.8 f) and will lead to a decrease in sediment  $^{231}\text{Pa}/^{230}\text{Th}$ , which is  
419 opposite to the effect of reduced AMOC. P-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  shows an  
420 initial decrease in first 200 years (Fig.9 d, e, and f, red dash lines) caused by the  
421 reduced opal productivity. But this decrease trend is reversed eventually, suggesting  
422 that the influence of particle flux change is overwhelmed by the effect of reduced  
423 AMOC. In the long run, most regions in the subtropical and mid-latitude Atlantic  
424 show increased sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in HOSING (Fig.10 d), indicating the dominant  
425 effect of reduced AMOC. However, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  at  $40^{\circ}\text{N}$  west Atlantic,  
426 where opal productivity is maximum during AMOC\_on, show a decrease from  
427 AMOC\_on to AMOC\_off (Fig.9 d and Fig.10 d). During AMOC\_on, the opal productivity  
428 maximum at  $40^{\circ}\text{N}$  west Atlantic lead to regional maximum sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
429 because of the particle flux effect (Fig. 4). During AMOC\_off, this opal productivity  
430 maximum is eliminated (Fig.8 e) and there is no more extra  $^{231}\text{Pa}$  supplied by  
431 surroundings to this region, which leads to a decrease in sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . This  
432 decrease in sediment  $^{231}\text{Pa}/^{230}\text{Th}$  caused by productivity change is greater than the  
433 increase caused by the reduced AMOC. Therefore, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  experiences  
434 a decrease from AMOC\_on to AMOC\_off at this location (Fig.9 d and Fig.10 d). Our  
435 results suggest that although the circulation effect is more dominant than the  
436 particle flux change in controlling sediment  $^{231}\text{Pa}/^{230}\text{Th}$  on long time scale over  
437 most of North Atlantic (Fig. 11), particle flux change can be important on short time  
438 scale and in high productivity regions. With p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ ,  
439 our model can help to detangle the circulation effect and particle flux effect.  
440

441 It is suggested that the particulate  $^{231}\text{Pa}/^{230}\text{Th}$  response to the change of  
442 AMOC depends on the location and depth. Above 2km and high latitude North  
443 Atlantic, particulate  $^{231}\text{Pa}/^{230}\text{Th}$  decreases with the increased AMOC (Rempfer et al.,  
444 2017). Our results are consistent with this finding (Fig. 12 a and b). Both p-fixed and  
445 p-coupled particulate  $^{231}\text{Pa}/^{230}\text{Th}$  show similar patterns of change from AMOC\_on to  
446 AMOC\_off: decrease in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  at shallow depth and north of  $60^{\circ}\text{N}$   
447 and increase in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  below 2km and south of  $60^{\circ}\text{N}$  during

448 AMOC\_off. Therefore, sediment depth should also be taken into consideration when  
449 interpreting sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . Since the pattern in p-coupled is similar to the  
450 pattern in p-fixed, the opposite particulate  $^{231}\text{Pa}/^{230}\text{Th}$  changes in shallow and deep  
451 North Atlantic is associated with AMOC change. During AMOC\_on, upper limb of  
452 AMOC (about upper 1km) transport water northward, which provides extra  $^{231}\text{Pa}$  to  
453 North Atlantic and particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is larger than the production ratio of  
454 0.093. In contrast, the lower limb of AMOC (2km-3km) features southward  
455 transport, which transports  $^{231}\text{Pa}$  to the Southern Ocean and particulate  $^{231}\text{Pa}/^{230}\text{Th}$   
456 is smaller than the production ratio of 0.093 (Fig. 12 solid). Particulate  $^{231}\text{Pa}/^{230}\text{Th}$   
457 decreases with depth (Fig. 12 c solid). During AMOC\_off, ocean transport of  $^{231}\text{Pa}$  is  
458 greatly reduced. Therefore, shallow (deep) depth experiences a decrease (increase)  
459 in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  and the vertical gradient in the particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is  
460 also greatly reduced (Fig. 12 c dash). Our results support that the depth dependence  
461 of particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is mainly caused by lateral transport of  $^{231}\text{Pa}$  by  
462 circulation (Gherardi et al., 2009; Lippold et al., 2011, 2012a; Luo et al., 2010;  
463 Rempfer et al., 2017).

464 Overall, our model is able to simulate the correct magnitude of the sediment  
465  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to the freshwater forcing. Change of circulation has the  
466 dominant influence on sediment  $^{231}\text{Pa}/^{230}\text{Th}$  on long time scale over most of regions  
467 in the idealized hosing experiment, although the detailed difference between p-fixed  
468 and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to freshwater forcing in  
469 different locations can be complicated.

470

471

## 472 **5. Summary**

473  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  have been implemented in the ocean model of the CESM in  
474 both the p-coupled and p-fixed forms. Our control experiment under present day  
475 climate forcing is able to simulate most  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  water column activity and  
476 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio consistent with observations by using the  
477 parameters that are suggested by Chase et al., (2002) and used in Siddall et al.

478 (2005). Our sensitivity experiments with varying parameters suggest that these  
479 parameters are of the right order of magnitude.

480 Furthermore, our model is able to simulate the overall sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
481 ratio change in the North Atlantic with a magnitude comparable to the  
482 reconstruction in response to the collapse of AMOC, although the detailed response  
483 can be complicated in different regions. Finally, the p-fixed form is able to capture  
484 many major features of that of the p-coupled form over large ocean areas on long  
485 time scale, although the two forms can also differ significantly in some regions,  
486 especially the region with high opal productivity.

487 However, our implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be further improved by  
488 including nepheloid layers to better simulate water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity  
489 as in Rempfer et al., 2017. In addition, partition coefficient for different particles can  
490 be further tuned in the future, which can improve our understanding of the affinity  
491 of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  to different particles, complementing the limited observational  
492 studies available (e.g. Chase et al., 2002; Scholten et al., 2005; Walter et al., 1997).  
493 Nevertheless, as the first attempt to implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the CESM with  
494 both p-fixed and p-coupled versions, our model can serve as a useful tool to improve  
495 our understanding of the processes of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  and also interpretations of  
496 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions for past ocean circulation and climate  
497 changes.

498

499

500 **Code availability:**

501 The  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  isotope source code of both p-fixed and p-coupled versions for  
502 CESM1.3 is included as supplementary material here.

886 Table 2. Partition coefficients for different particle types and residence time for  
887  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in different experiments. Partition coefficients used in CTRL follows  
888 (Chase et al., 2002; Siddall et al., 2005). Both p-coupled and p-fixed versions are  
889 enabled in CTRL, which yields identical results (discussed in section 4.1). Only p-  
890 fixed version is enabled in Exp\_1 and Exp\_2. The residence time ( $\tau$ ) is for p-fixed  
891 version in each experiment.

919     Figures:

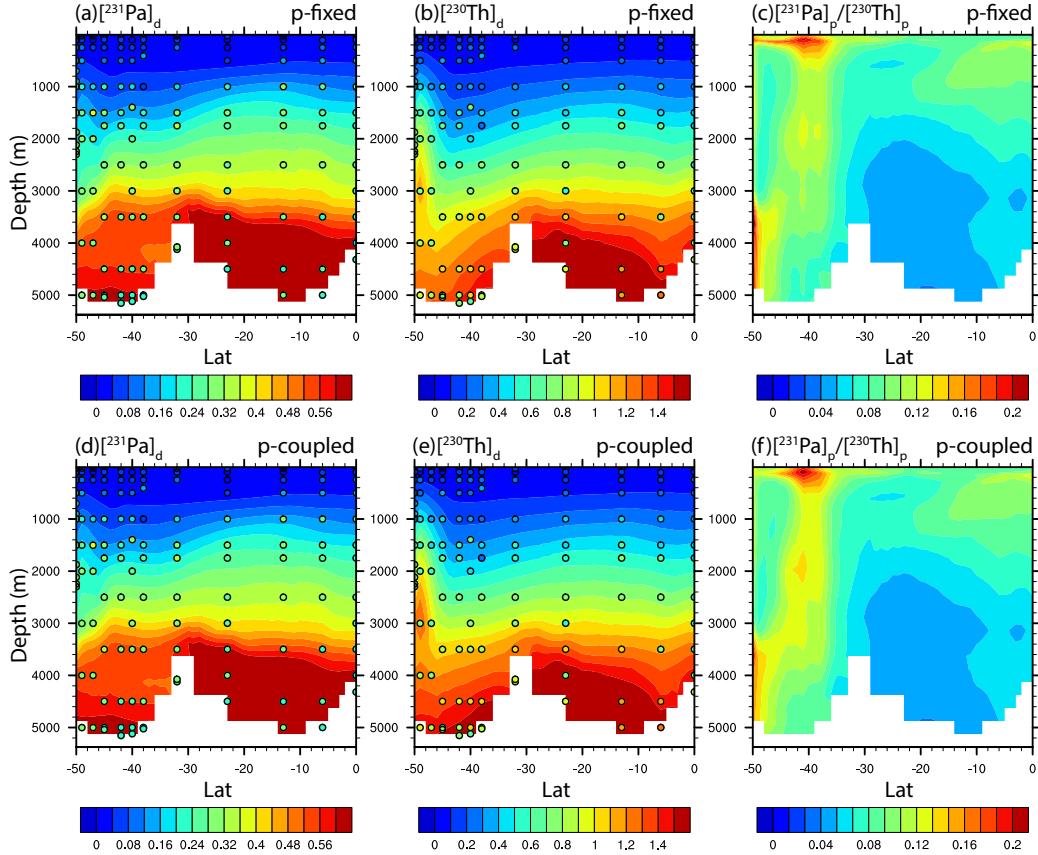

920

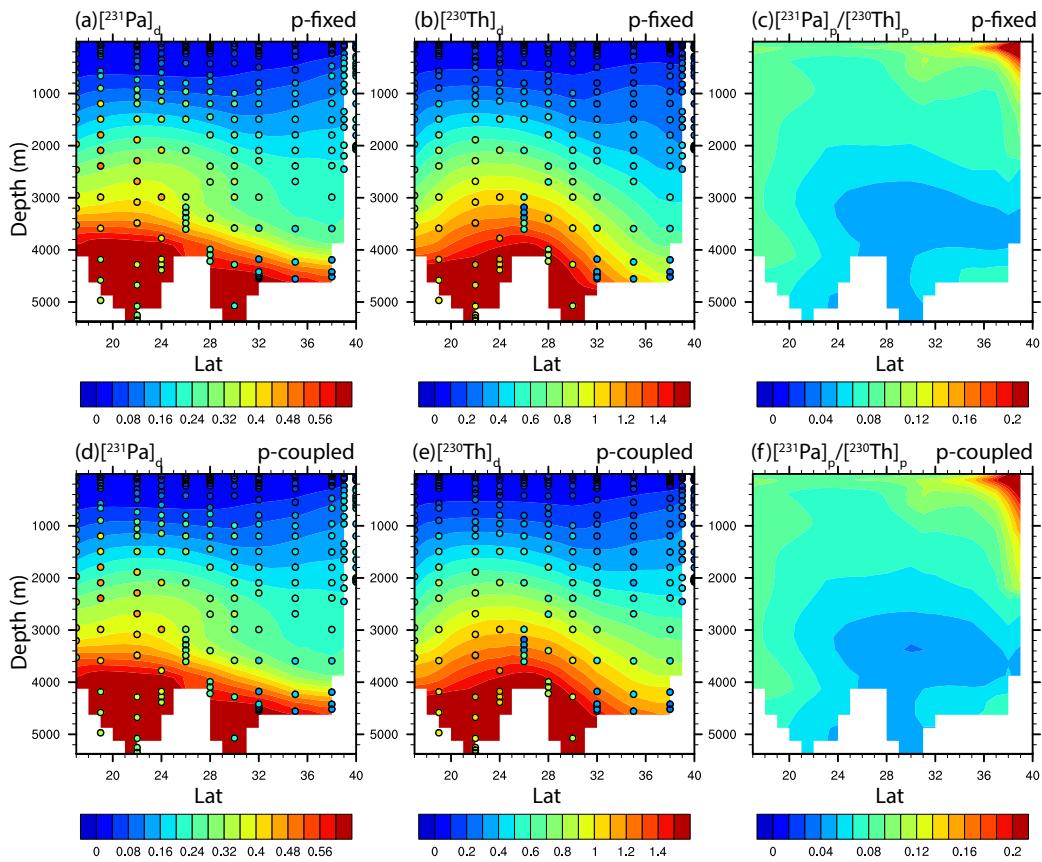

921 Figure 1. Annual mean particle fluxes in CESM. (a)  $\text{CaCO}_3$  flux at 105m ( $\text{mol m}^{-2} \text{yr}^{-1}$ ).

922 (b) Opal flux at 105m ( $\text{mol m}^{-2} \text{yr}^{-1}$ ). (c) POC flux at 105m ( $\text{mol m}^{-2} \text{yr}^{-1}$ ).

923

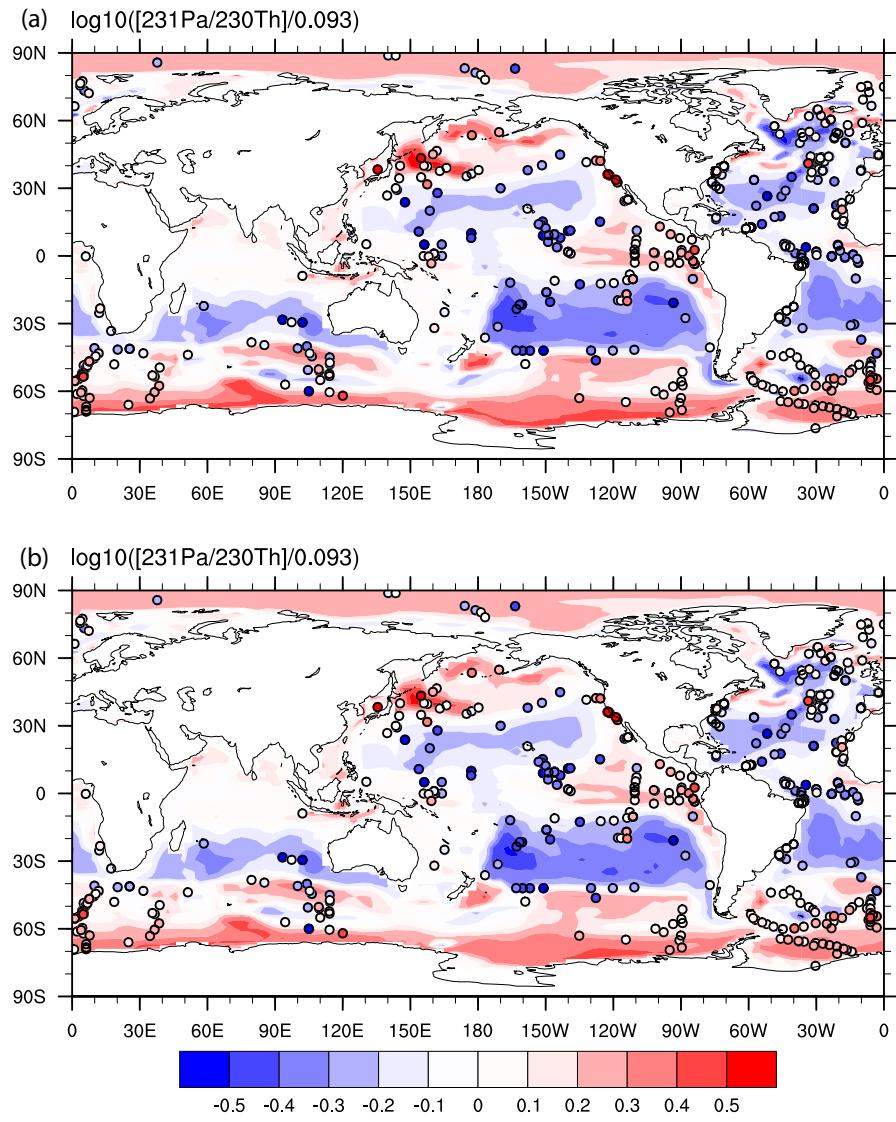

926 Figure 2. Dissolved  $^{231}\text{Pa}$ , dissolved  $^{230}\text{Th}$  and particulate  $^{231}\text{Pa}/^{230}\text{Th}$  in CTRL along  
 927 GEOTRACES transect GA02S (Deng et al., 2014) (the track is indicated in Fig. S4) for  
 928 both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . Observations of dissolved  $^{231}\text{Pa}$  and  
 929  $^{230}\text{Th}$  activity are superimposed using the same colormap.

930

931 Figure 3. Dissolved  $^{231}\text{Pa}$ , dissolved  $^{230}\text{Th}$  and particulate  $^{231}\text{Pa}/^{230}\text{Th}$  in CTRL along  
 932 GEOTRACES transect GA03 (Hayes et al., 2015) (the track is indicated in Fig. S4) for  
 933 both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . Observations of dissolved  $^{231}\text{Pa}$  and  
 934  $^{230}\text{Th}$  activity are superimposed using the same colormap.

935

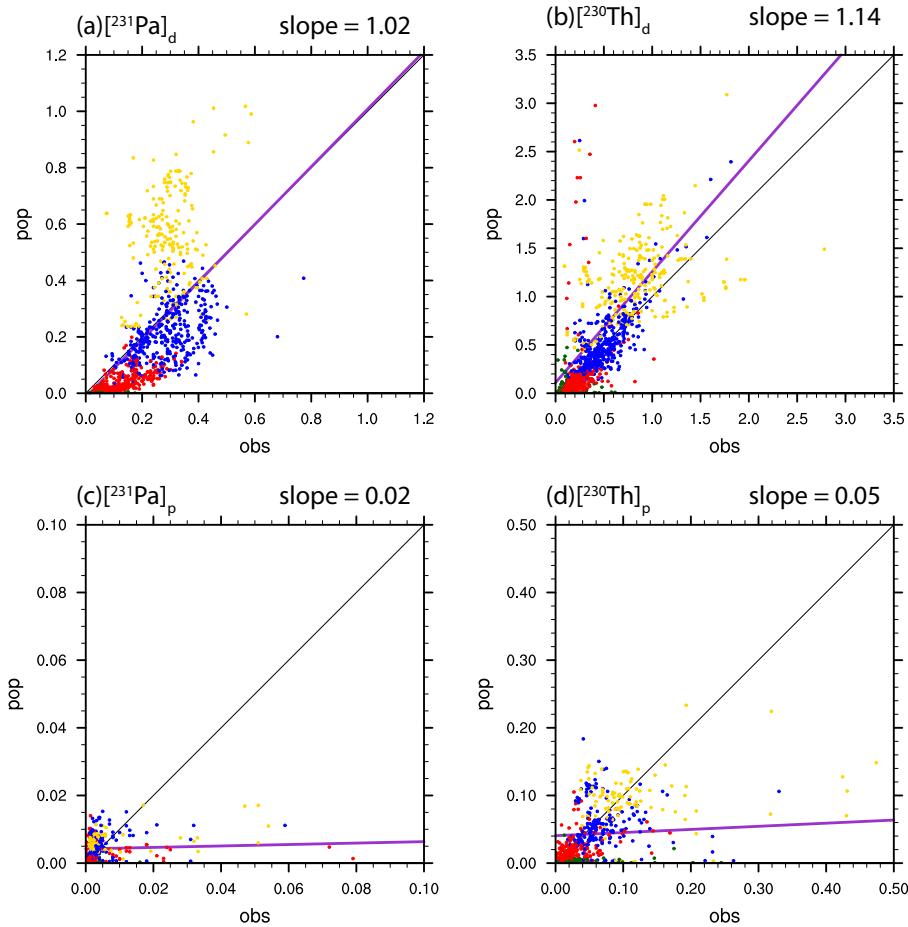

936 Figure 4. Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in CTRL for both p-fixed (a) and p-  
 937 coupled version (b). Observations are attached as filled cycles using the same color  
 938 map. The  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is plotted relative to the production ratio of  
 939 0.093 on a  $\log_{10}$  scale.

940

941

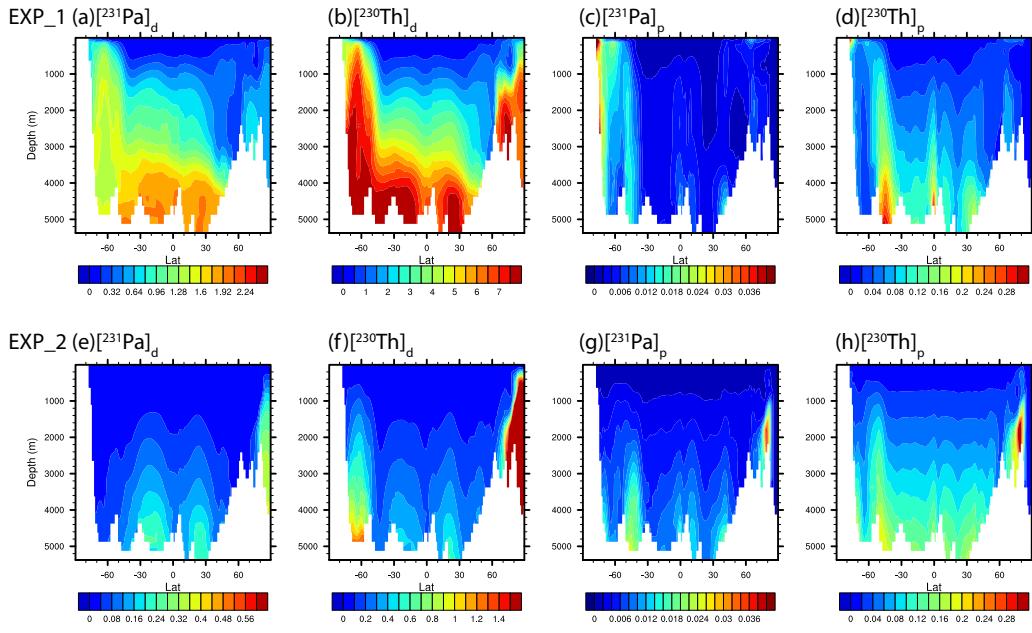

942

943

944

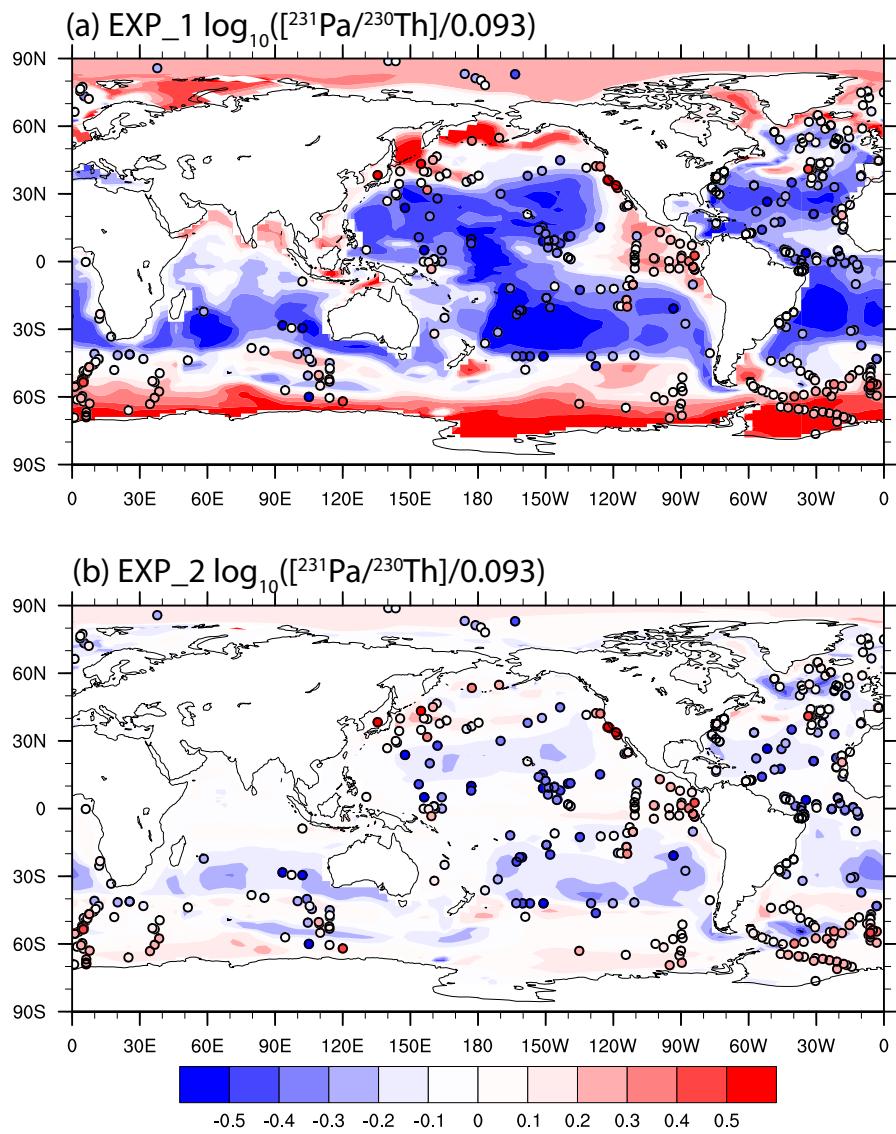

945 Figure 5. Scatter plot of global dissolved and particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  between  
946 observation and CTRL (p-fixed) (unit: dpm/m<sup>3</sup>). (a) dissolved  $^{231}\text{Pa}$ ; (b) particulate  
947  $^{231}\text{Pa}$ ; (c) dissolved  $^{230}\text{Th}$ ; (d) particulate  $^{230}\text{Th}$ . Observations in different depth  
948 range are indicated by different colors: green for 0-100m; red for 100m-1000m;  
949 blue for 1000m-3000m and yellow for deeper than 3000m. Purple line is the least  
950 squared linear regression line and slope is the linear regression coefficient.

951

952 Figure 6. Atlantic zonal mean dissolved and particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in EXP\_1 and  
 953 EXP\_2 (unit: dpm/m<sup>3</sup>). EXP\_1: (a) dissolved  $^{231}\text{Pa}$ ; (b) dissolved  $^{230}\text{Th}$ ; (c)  
 954 particulate  $^{231}\text{Pa}$ ; (d) particulate  $^{230}\text{Th}$ . EXP\_2: (e) dissolved  $^{231}\text{Pa}$ ; (f) dissolved  
 955  $^{230}\text{Th}$ ; (g) particulate  $^{231}\text{Pa}$ ; (h) particulate  $^{230}\text{Th}$ .

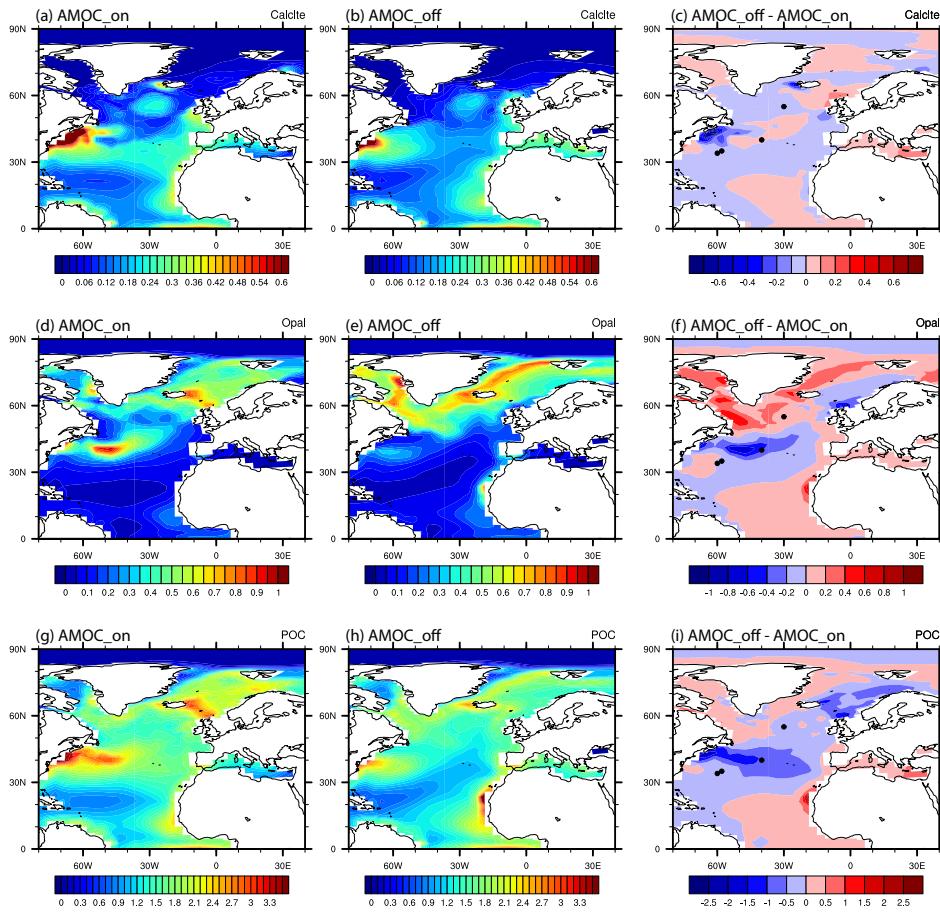

956

957

958 Figure 7. Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in EXP\_1 (a) and EXP\_2 (b).  
 959 Observations are attached as filled cycles using the same color map. The  $^{231}\text{Pa}/^{230}\text{Th}$   
 960 activity ratio is plotted relative to the production ratio of 0.093 on a  $\log_{10}$  scale.

961

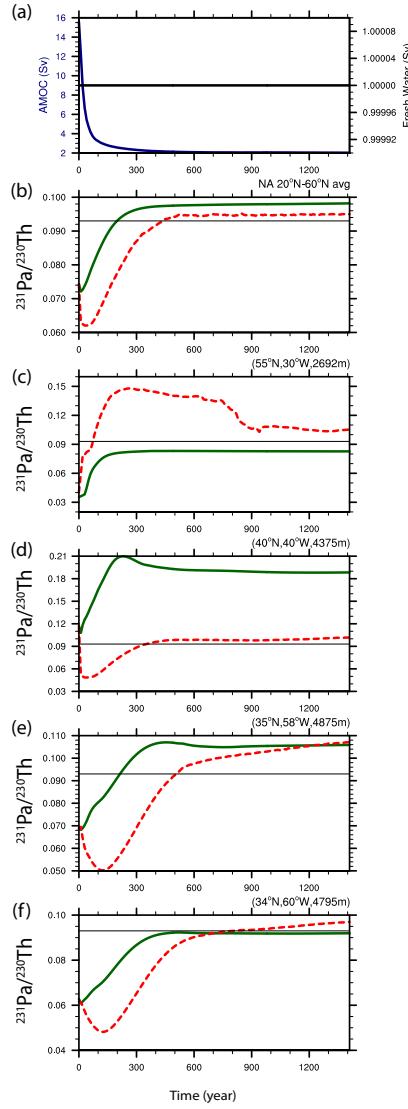

962

963 Figure 8. Comparison of particle fluxes between AMOC\_on and AMOC\_off.  $\text{CaCO}_3$  flux  
 964 at 105m ( $\text{mol m}^{-2} \text{yr}^{-1}$ ) during AMOC\_on (a), AMOC\_off (b) and difference between  
 965 AMOC\_off and AMOC\_on. (b) Opal flux at 105m ( $\text{mol m}^{-2} \text{yr}^{-1}$ ) during AMOC\_on (d),  
 966 AMOC\_off (e) and difference between AMOC\_off and AMOC\_on (f). POC flux at 105m  
 967 ( $\text{mol m}^{-2} \text{yr}^{-1}$ ) during AMOC\_on (g), AMOC\_off (h) and difference between AMOC\_off  
 968 and AMOC\_on (i).

969

970

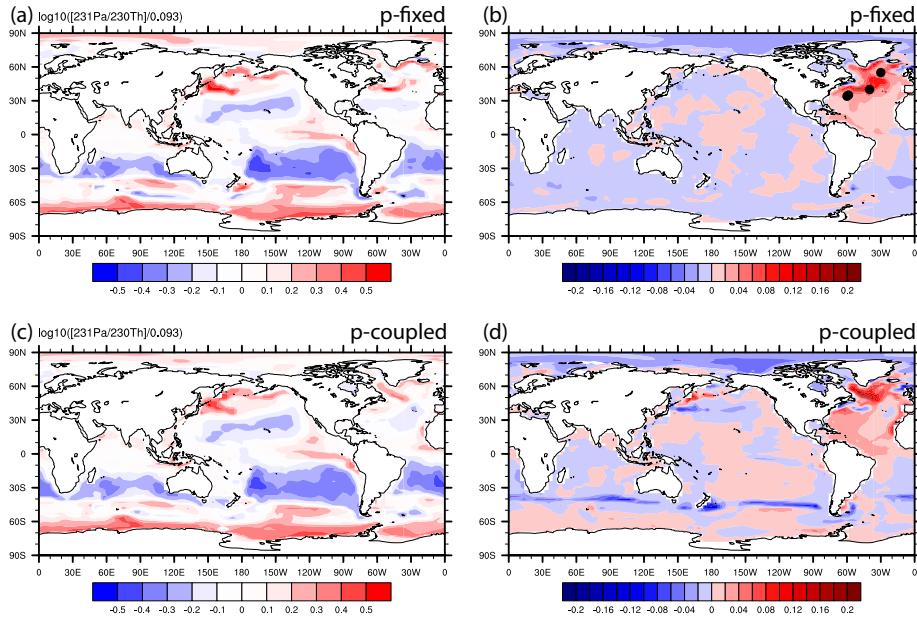

971

972

973 Figure 9. Time evolutions in HOSING. (a) Freshwater forcing (black) and AMOC  
 974 strength (navy), which is defined as the maximum of the overturning  
 975 streamfunction below 500m in the North Atlantic. (b) North Atlantic average  
 976 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio from 20°N to 60°N: p-fixed (green) and p-  
 977 coupled (red). Production ratio of 0.093 is indicated by a solid black line (similar in  
 978 c, d, e and f). (c) Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio at (55°N, 30°W). (d) Sediment  
 979  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio at (40°N, 40°W). (e) Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio at  
 980 (35°N, 58°W). (f) Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio at (34°N, 60°W). (e) and (f) are  
 981 near Bermuda Rise. Locations of each site are shown as dots in Fig. 8b.

982

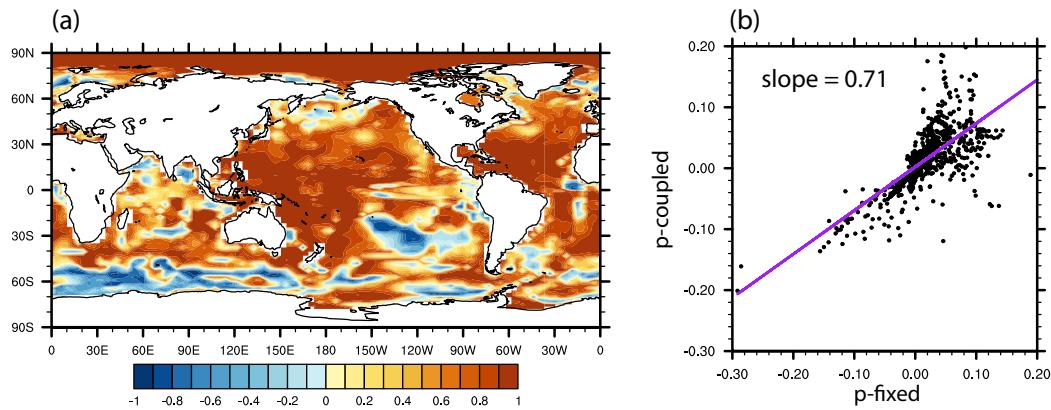

983

984

985 Figure 10. Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio during AMOC off state and the  
 986 difference between AMOC off and CTRL. (a) P-fixed  $\log_{10}([^{231}\text{Pa}/^{230}\text{Th}]/0.093)$  in  
 987 AMOC\_off. (b) Difference of p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio between  
 988 AMOC\_off and AMOC\_on. (c) and (d) are similar to (a) and (b) for p-coupled  
 989 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio. Black dots in (b) shows the locations of sites in  
 990 Fig. 9 from North to South.

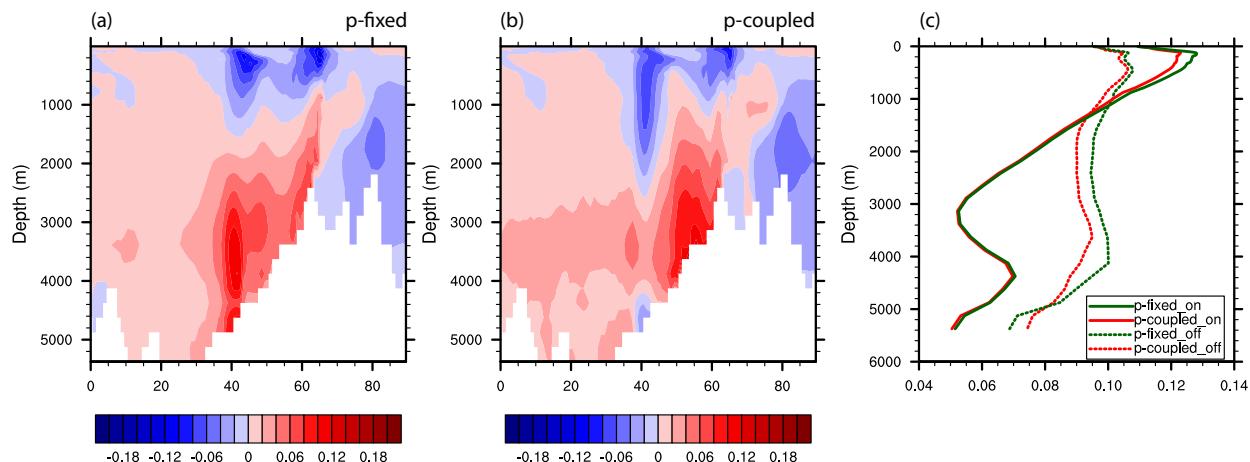

991

992

993 Figure 11. (a) Correlation of p-fixed and p-coupled evolution of sediment  
994  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in HOSING. (b) Scatter plot of p-fixed and p-coupled  
995 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio change from AMOC\_on to AMOC\_off in the  
996 Atlantic and the Southern Ocean ( $70^{\circ}\text{W}-20^{\circ}\text{E}$ ). Purple line is the least squared linear  
997 regression line and slope is the linear regression coefficient.

998

999

1000 Figure 12. Difference of Atlantic zonal mean particulate  $^{231}\text{Pa}/^{230}\text{Th}$  between  
1001 AMOC\_off and AMOC\_on: (a) p-fixed and (b) p-coupled. (c) North Atlantic ( $20^{\circ}\text{N}$ -  
1002  $60^{\circ}\text{N}$ ) average profile during AMOC\_on (solid) and AMOC\_off (dash) for p-fixed  
1003 (green) and p-coupled (red) particulate  $^{231}\text{Pa}/^{230}\text{Th}$ .
